

Network Flow

Network Flow terminology

Network flow is similar to finding how much water we can bring from a “source” to a “sink” (infinite) (intermediates cannot “hold” water)

Network Flow terminology

Definitions:

$c(u,v)$: edge capacity, $c(u,v) \geq 0$

$f(u,v)$: flow from u to v s.t.

1. $0 \leq f(u,v) \leq c(u,v)$

2. $\sum_v f(u,v) = \sum_v f(v,u)$

flow out
= flow in

s : a source, $\sum_v f(s,v) \geq \sum_v f(v,s)$

t : a sink, $\sum_v f(t,v) \leq \sum_v f(v,t)$

Network Flow terminology

Definitions (part 2):

$$|f| = \sum_v f(s,v) - \sum_v f(v,s)$$

^ amount of flow from source

Want to maximize $|f|$ for the
maximum-flow problem

Network Flow terminology

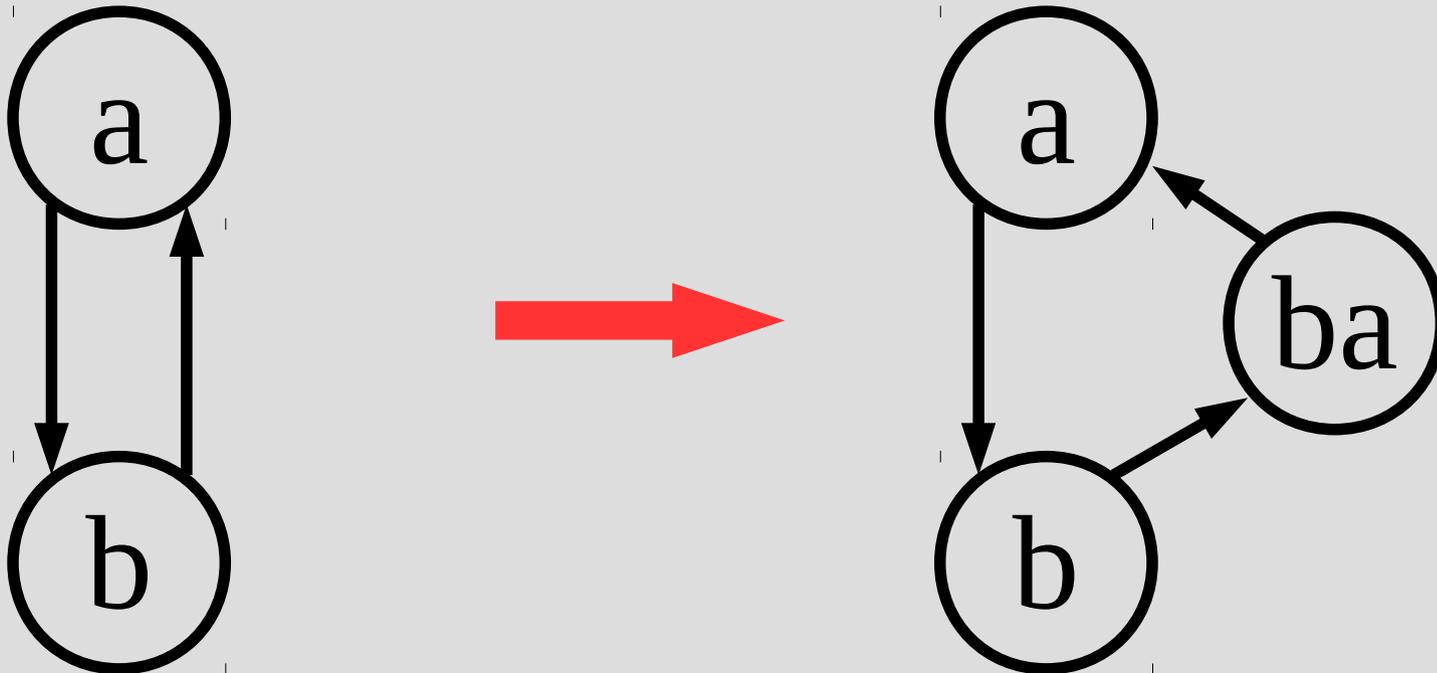

Graph restrictions:

1. If there is an edge (u,v) , then there cannot be edge (v,u)
2. Every edge is on a path from source to sink
3. One sink and one source

(None are really restrictions)

Network Flow terminology

1. If there is an edge (u,v) , then there cannot be edge (v,u)

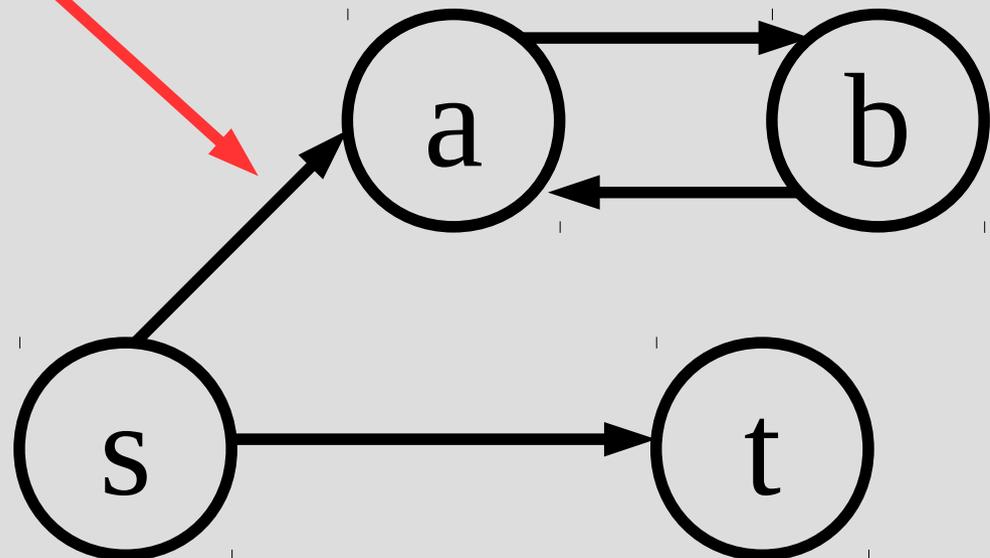

Network Flow terminology

2. Every edge is on a path from source to sink

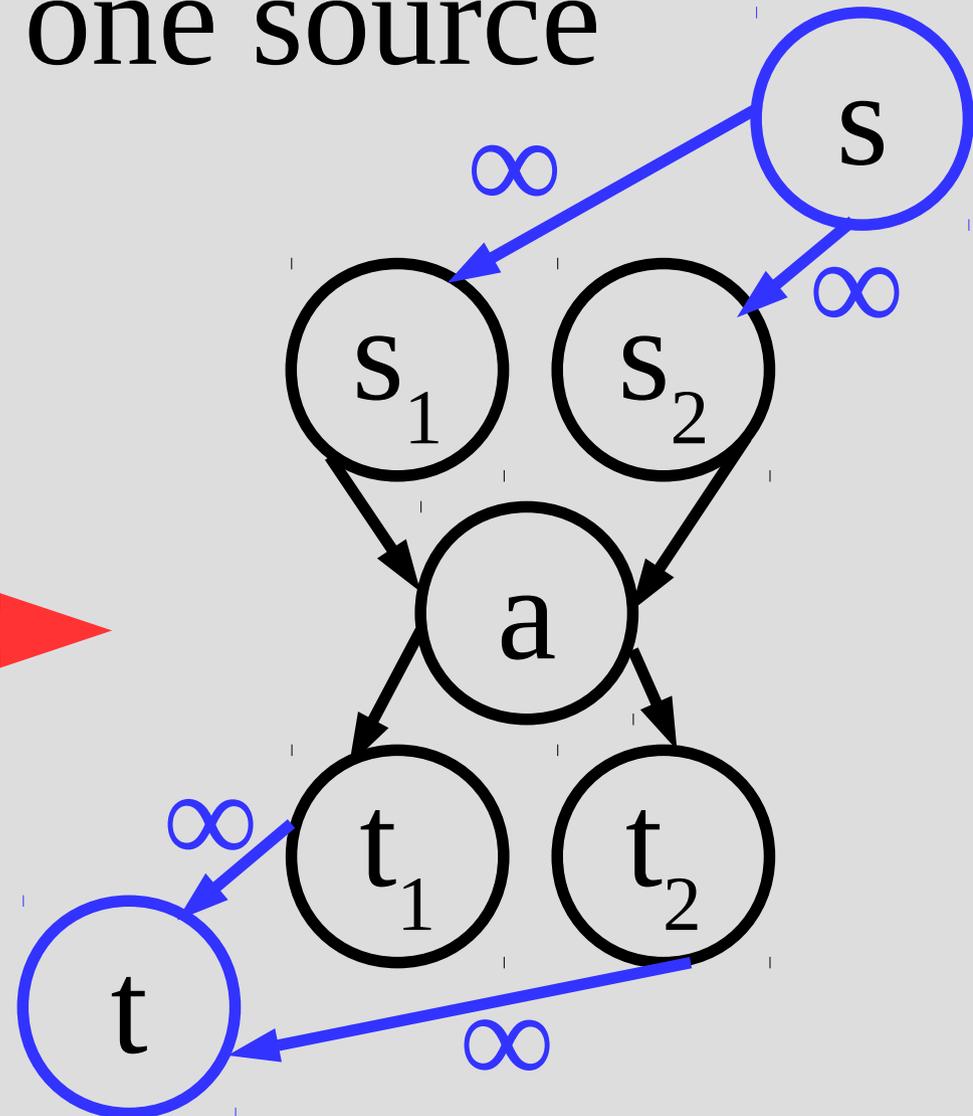

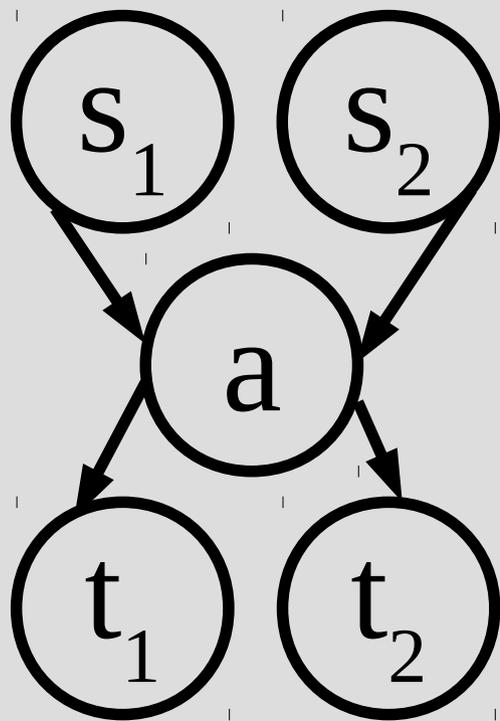

flow in = flow out,
only possible
flow in is 0

(worthless
edge)

Network Flow terminology

3. One sink and one source

Ford-Fulkerson

Idea:

1. Find a path from source to sink
2. Add maximum flow along path
(minimum capacity on path)
3. Repeat

Note: this path needs to be found in a
“residual” graph

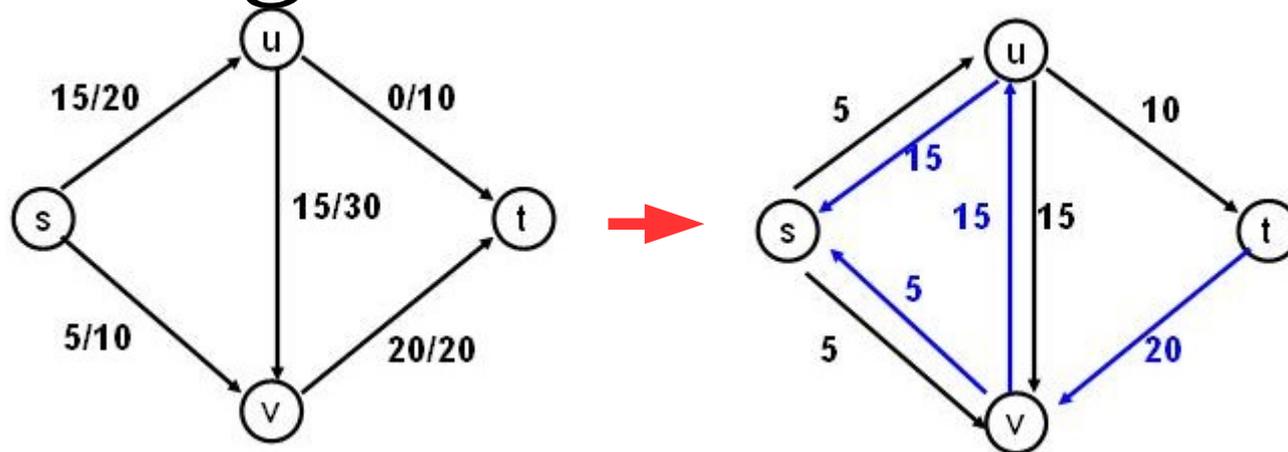

Ford-Fulkerson

What is a residual graph?

Forward edges = capacity left

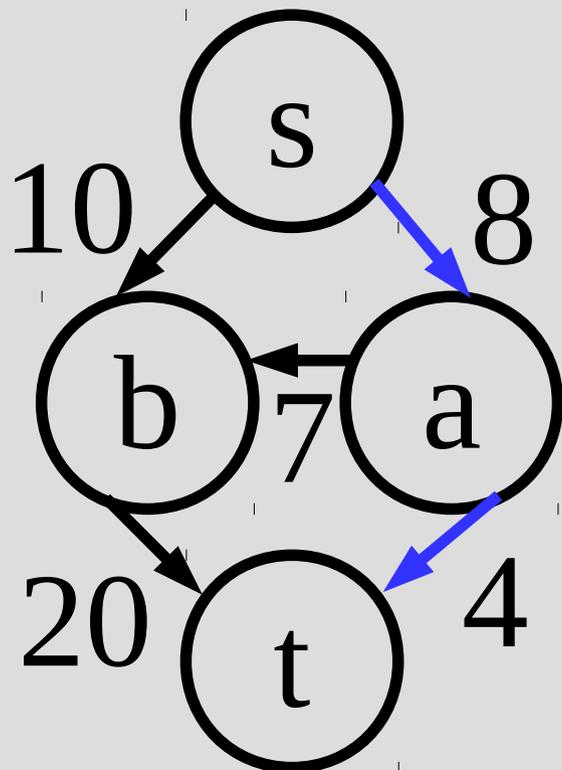

Back edges = flow

Original Residual

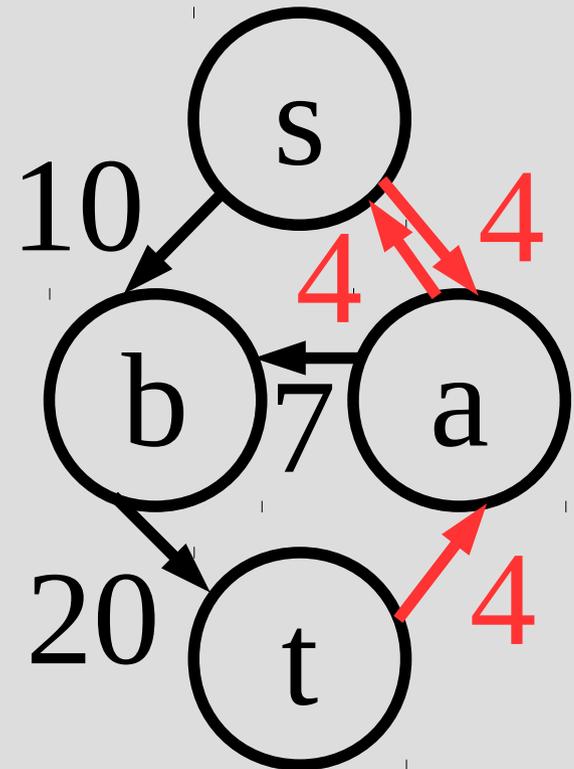

Ford-Fulkerson

Idea: Find a way to add some flow, modify graph to show this flow reserved... repeat.

Augment

Ford-Fulkerson

Ford-Fulkerson(G, s, t)

initialize network flow to 0

while (exists path from s to t)

 augment flow, f , in G along path

return f

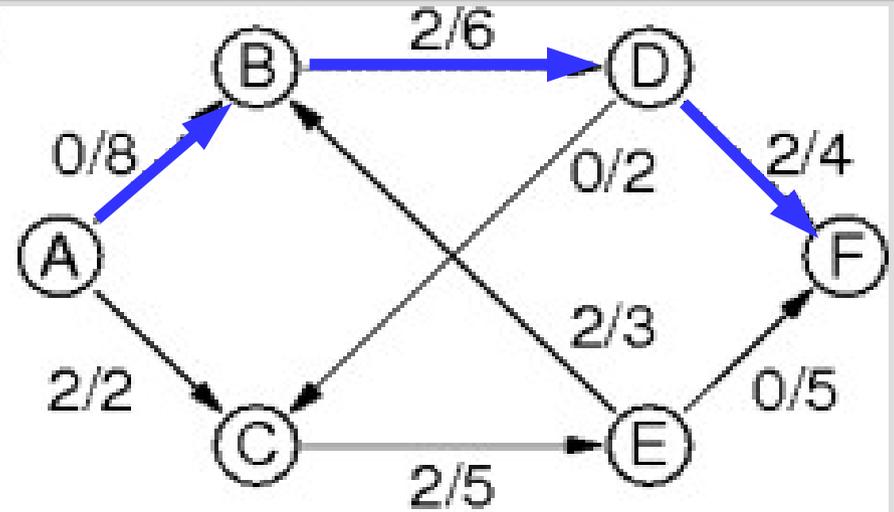

(Note: “augment flow” means add this flow to network)

Ford-Fulkerson

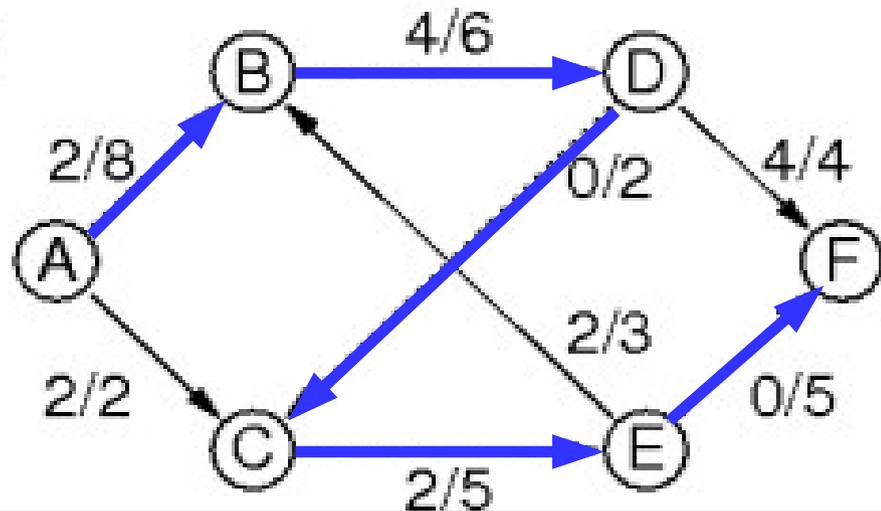

1:

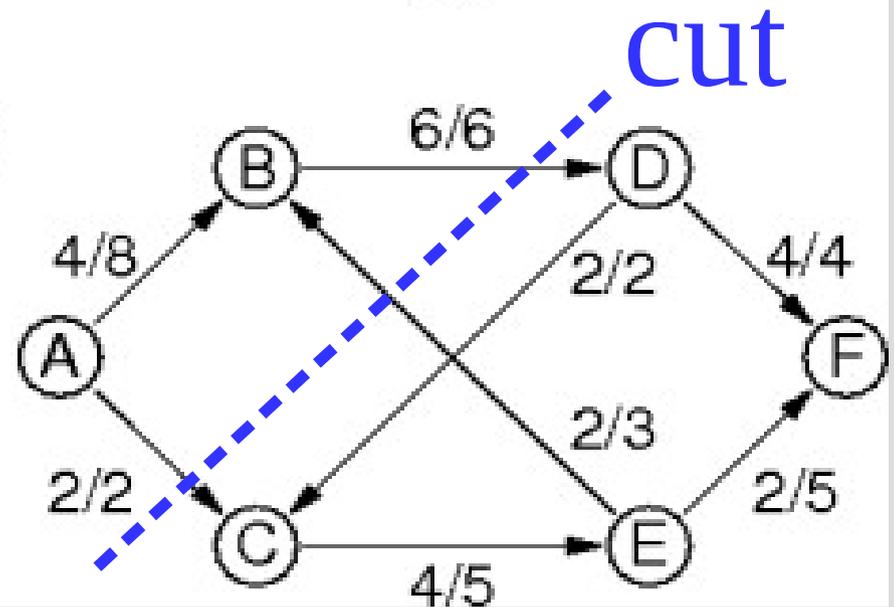

2:

3:

4:

Ford-Fulkerson

Subscript “f” denotes residual (or modified graph)

G_f = residual graph

E_f = residual edges

c_f = residual capacity

$c_f(u,v) = c(u,v) - f(u,v)$

$c_f(v,u) = f(v,u)$

“forward edge”
capacity - flow

“back edge”
just flow

Ford-Fulkerson

Ford-Fulkerson(G, s, t)

for: each edge (u, v) in $G.E$: $(u, v).f = 0$

while: exists path from s to t in G_f

find $c_f(p)$ // minimum edge cap. on path

for: each edge (u, v) in p

if (u, v) in E : $(u, v).f = (u, v).f + c_f(p)$

else: $(u, v).f = (u, v).f - c_f(p)$

Ford-Fulkerson

Runtime:

How hard is it to find a path?

How many possible paths could you find?

Ford-Fulkerson

Runtime:

How hard is it to find a path?

- $O(E)$ (via BFS or DFS)

How many possible paths could you find?

- $|f^*|$ (paths might use only 1 flow)

.... so, $O(E |f^*|)$

Ford-Fulkerson

$$(f \uparrow f')(u,v) = \text{flow } f \text{ augmented by } f'$$
$$(f \uparrow f')(u,v) = f(u,v) + f'(u,v) - f'(v,u)$$

Lemma 26.1: Let f be the flow in G , and f' be a flow in G_f , then $(f \uparrow f')$ is a flow in G with total amount:

$$|f \uparrow f'| = |f| + |f'|$$

Proof: pages 718-719

Ford-Fulkerson

For some path p :

$$c_f(p) = \min(c_f(u,v) : (u,v) \text{ on } p)$$

$\wedge\wedge$ (capacity of path is smallest edge)

Claim 26.3:

Let $f_p = c_f(p)$, then

$$|f \uparrow f_p| = |f| + |f_p|$$

Ford-Fulkerson

More bad notation:

$c(u,v)$ = capacity of an edge
if u and v are single vertexes

$c(S,T)$ = capacity across a cut
if S and T are sets of vertexes

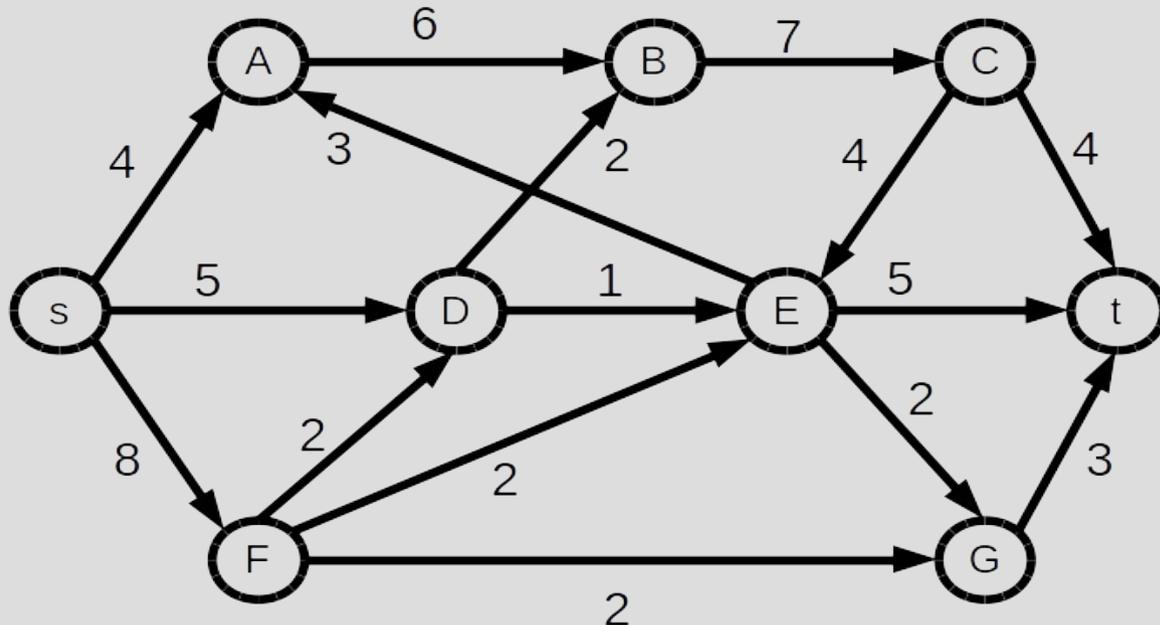

... Similarly for $f(u,v)$ and $f(S,T)$

Max flow, min cut

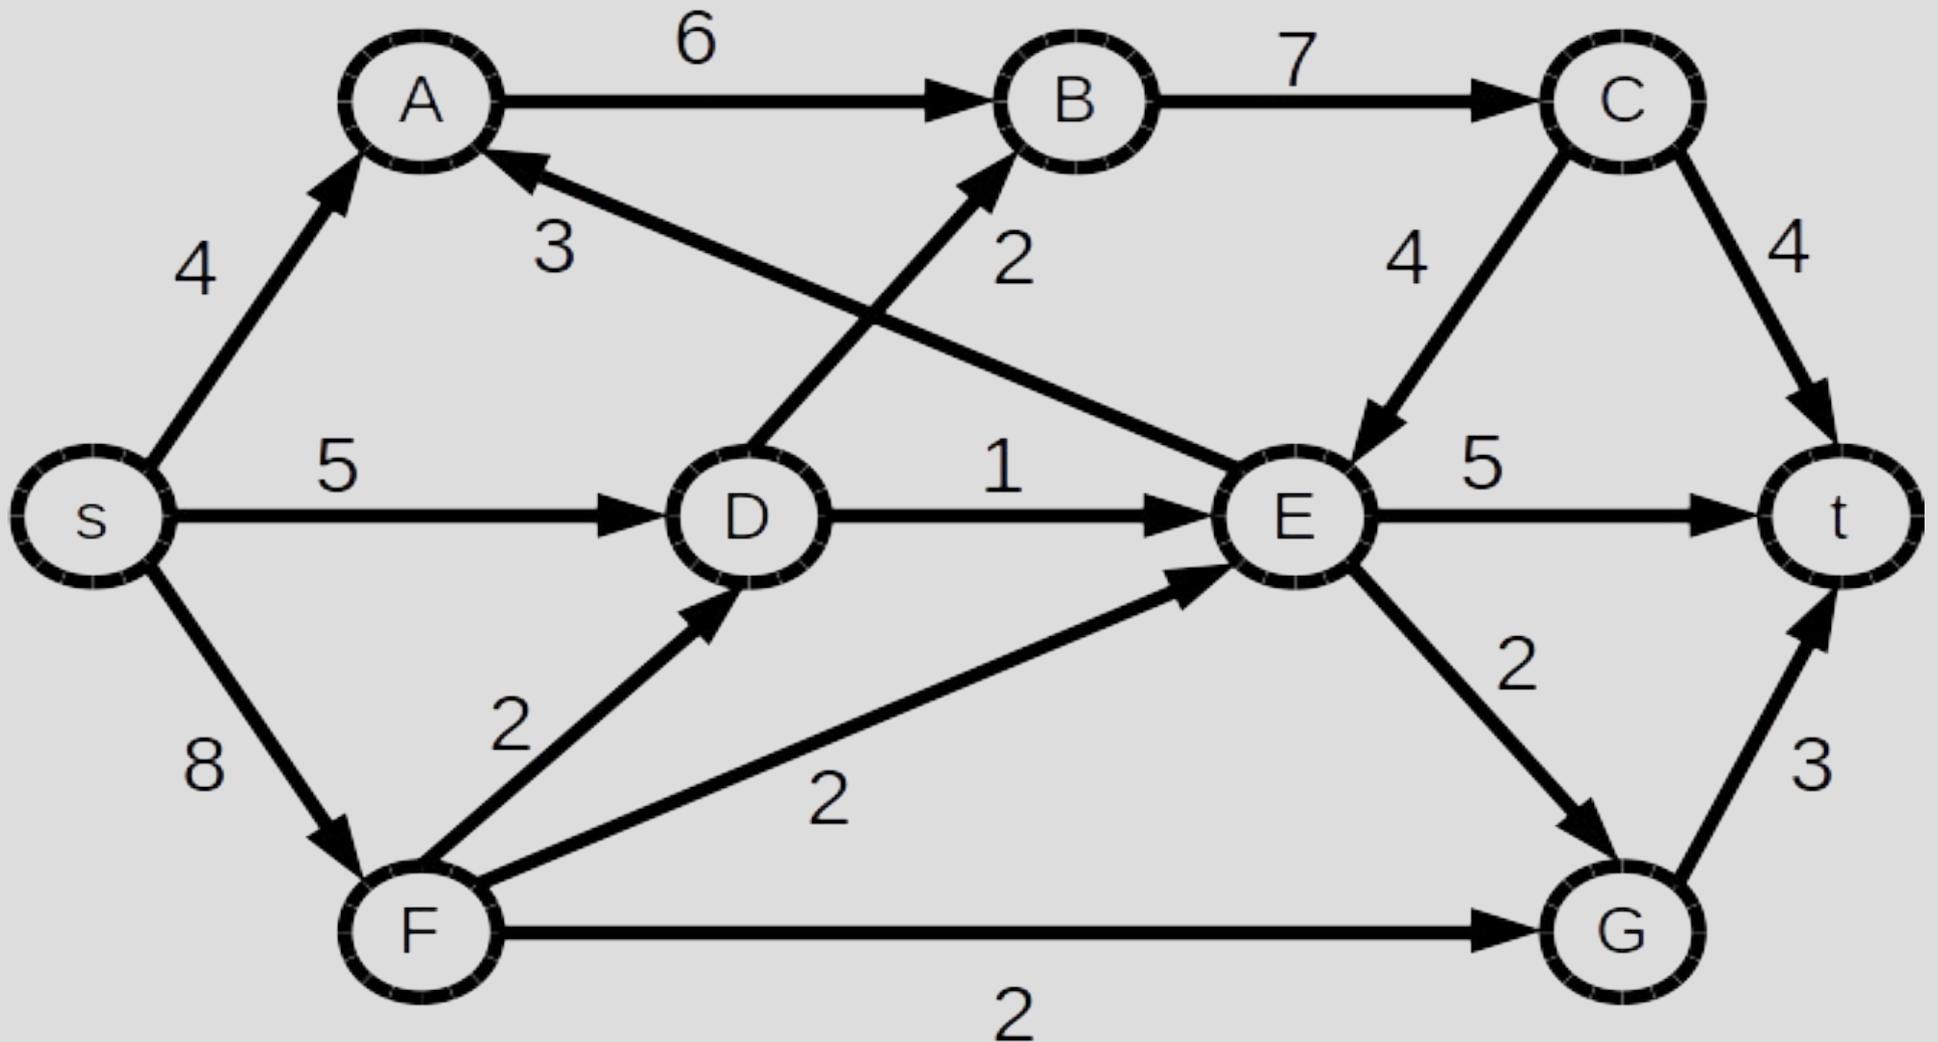

Relationship between cuts and flows?

$$c(S,T) = \sum_{u \text{ in } S} \sum_{v \text{ in } T} c(u,v)$$

$$f(S,T) = \sum_{u \text{ in } S} \sum_{v \text{ in } T} f(u,v) - \sum_u \sum_v f(v,u)$$

Max flow, min cut

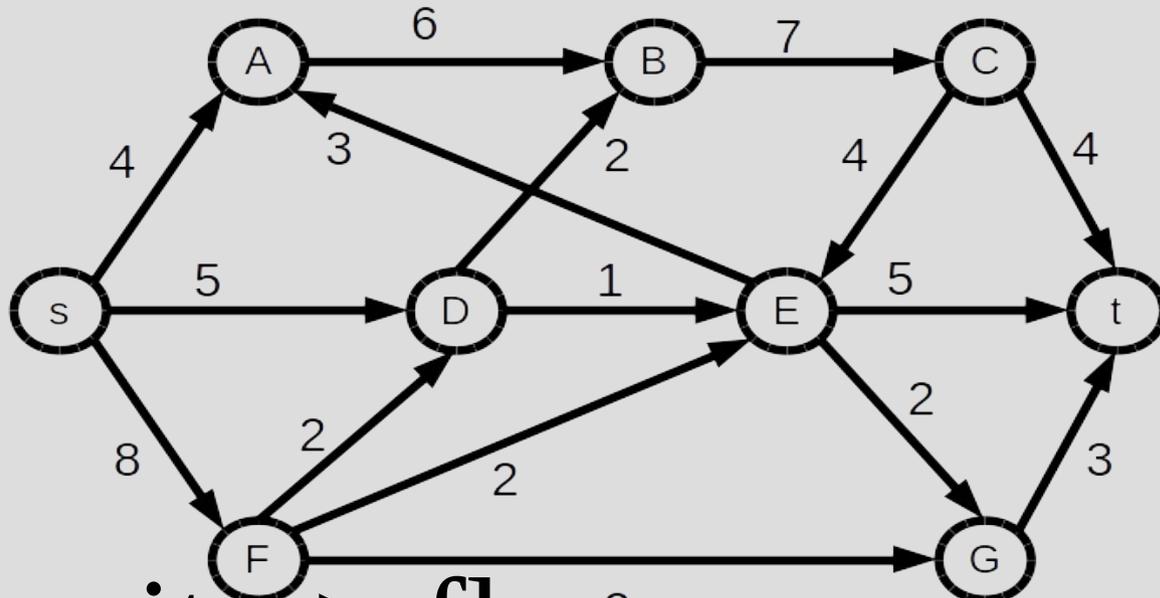

Max flow, min cut

Relationship between cuts and flows?

$$c(S,T) = \sum_{u \text{ in } S} \sum_{v \text{ in } T} c(u,v)$$

$$f(S,T) = \sum_{u \text{ in } S} \sum_{v \text{ in } T} f(u,v) - \sum_{u \text{ in } T} \sum_{v \text{ in } S} f(v,u)$$

cut capacity \geq flows² across cut

Max flow, min cut

Lemma 26.4

Let (S,T) be any cut, then $f(S,T) = |f|$

Proof:

Page 722

(Kinda long)

Max flow, min cut

Corollary 26.5

Flow is not larger than cut capacity

Proof:

$$\begin{aligned} |\mathbf{f}| &= \sum_{\mathbf{u} \text{ in } S} \sum_{\mathbf{v} \text{ in } T} f(\mathbf{u}, \mathbf{v}) - \sum_{\mathbf{u}} \sum_{\mathbf{v}} f(\mathbf{v}, \mathbf{u}) \\ &\leq \sum_{\mathbf{u} \text{ in } S} \sum_{\mathbf{v} \text{ in } T} f(\mathbf{u}, \mathbf{v}) \\ &\leq \sum_{\mathbf{u} \text{ in } S} \sum_{\mathbf{v} \text{ in } T} c(\mathbf{u}, \mathbf{v}) \\ &= c(S, T) \end{aligned}$$

Max flow, min cut

Theorem 26.5

All 3 are equivalent:

1. f is a max flow
2. Residual network has no aug. path
3. $|f| = c(S,T)$ for some cut (S,T)

 maximum network flow

Proof: = min cut (i.e. bottleneck)

Will show: $1 \Rightarrow 2, 2 \Rightarrow 3, 3 \Rightarrow 1$

Max flow, min cut

f is a max flow \Rightarrow Residual network has no augmenting path

Proof:

Assume there is a path p

$|f \uparrow f_p| = |f| + |f_p| > |f|$, which is a

contradiction to $|f|$ being a max flow

Max flow, min cut

Residual network has no aug. path \Rightarrow
 $|f| = c(S, T)$ for some cut (S, T)

Proof:

Let $S =$ all vertices reachable from
 s in G_f

u in S , v in $T \Rightarrow f(u, v) = c(u, v)$ else
there would be path in G_f

Max flow, min cut

Also, $f(v,u) = 0$ else $c_f(u,v) > 0$ and
again v would be reachable from s

$$\begin{aligned}
 f(S,T) &= \sum_{u \text{ in } S} \sum_{v \text{ in } T} f(u,v) - \sum_u \sum_v f(v,u) \\
 &= \sum_{u \text{ in } S} \sum_{v \text{ in } T} c(u,v) - \sum_u \sum_v 0 \\
 &= c(S,T)
 \end{aligned}$$

Max flow, min cut

$|f| = c(S,T)$ for some cut (S,T)
 $\Rightarrow f$ is a max flow

Proof:

$|f| \leq c(S,T)$ for all cuts (S,T)

Thus trivially true, as $|f|$ cannot get larger than $C(S,T)$

Edmonds-Karp

exists shortest path (BFS)

~~Ford-Fulkerson~~(G, s, t)

for: each edge (u, v) in $G.E$: $(u, v).f = 0$

while: ~~exists path from s to t in G_f~~

find $c_f(p)$ // minimum edge cap.

for: each edge (u, v) in p

if (u, v) in E : $(u, v).f = (u, v).f + c_f(p)$

else: $(u, v).f = (u, v).f - c_f(p)$

Edmonds-Karp

Lemma 26.7

Shortest path in G_f is non-decreasing

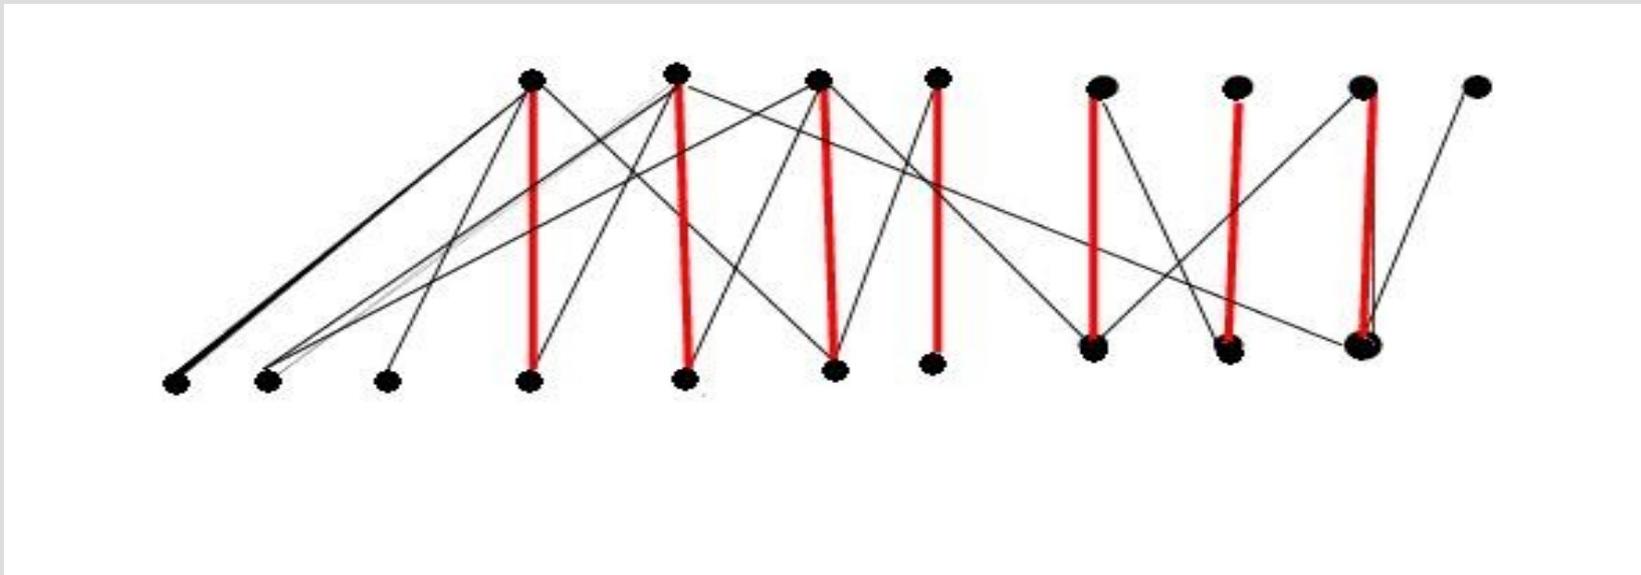

Theorem 26.8

Number of flow augmentations by Edmonds-Karp is $O(|V||E|)$

So, total running time: $O(|V||E|^2)$

Matching

Another application of network flow is maximizing (number of) matchings in a bipartite graph

Each node cannot be “used” twice

Matching

Add “super sink” and “super source”
(and direct edges source \rightarrow sink)
capacity = 1 on all edges
