Uninformed Search (Ch. 3-3.4)

Come on, I need answers...

HW due tonight

Writing 1 due next week

Search algorithm

To search, we will build a tree with the root as the initial state

function tree-search(root-node) fringe ← successors(root-node) while (notempty(fringe)) {node ← remove-first(fringe) state ← state(node) if goal-test(state) return solution(node) fringe ← insert-all(successors(node),fringe) } return failure end tree-search

Any problems with this?

Search algorithm

We can remove visiting states multiple times by doing this:

```
function tree-search(root-node)
fringe ← successors(root-node)
explored ← empty
while ( notempty(fringe) )
        {node ← remove-first(fringe)
            state ← state(node)
            if goal-test(state) return solution(node)
            explored ← insert(node,explored)
            fringe ← insert-all(successors(node),fringe, if node not in explored)
            }
        return failure
end tree-search
```

But this is still not necessarily all that great...

Search algorithm

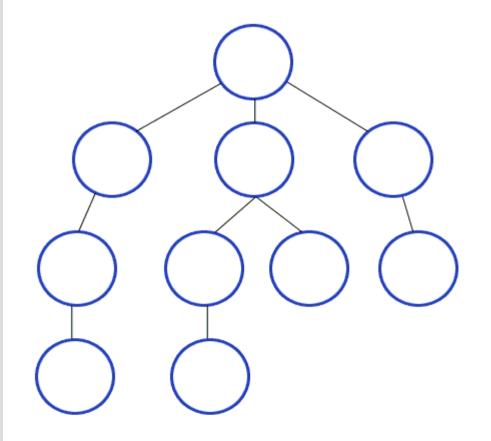

The search algorithms metrics/criteria: 1. Completeness (does it terminate with a valid solution)

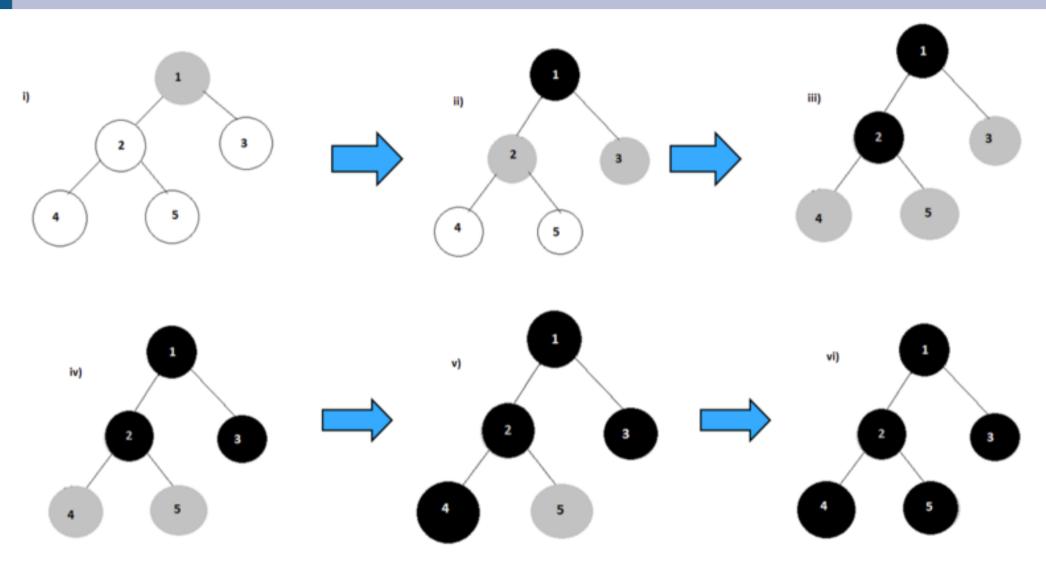

- 2. Optimality (is the answer the best solution)
- 3. Time (in big-O notation)
- 4. Space (big-O)

b = maximum branching factor d = minimum depth of a goal m =maximum length of any path(depth of tree)

<u>Breadth first search</u> checks all states which are reached with the fewest actions first

(i.e. will check all states that can be reached by a single action from the start, next all states that can be reached by two actions, then three...)

(see: https://www.youtube.com/watch?v=5UfMU9TsoEM)
(see: https://www.youtube.com/watch?v=nI0dT288VLs)

BFS can be implemented by using a simple FIFO (first in, first out) queue to track the fringe/frontier/unexplored nodes

Metrics for BFS:

Complete (i.e. guaranteed to find solution if exists) Non-optimal (unless uniform path cost) Time complexity = $O(b^d)$ Space complexity = $O(b^d)$

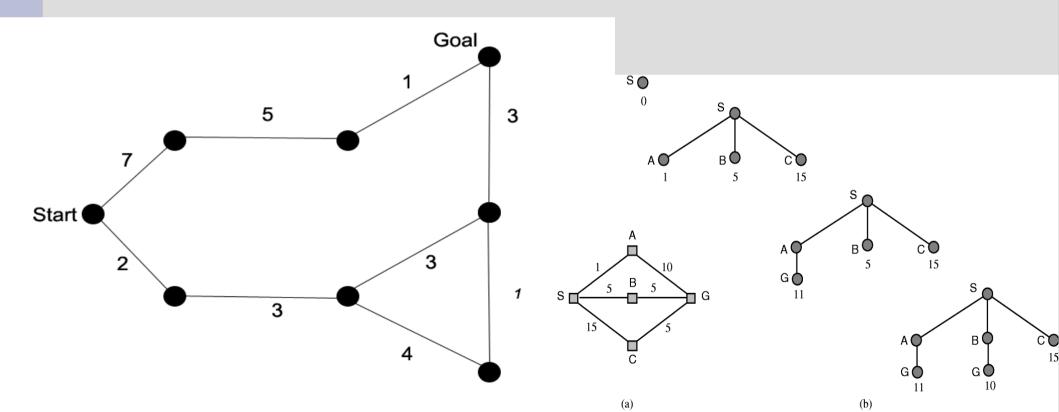

Exponential problems are not very fun, as seen in this picture:

| Depth | Nodes | (hemidder) | Time | N | Aemory |
|-------|-----------|------------|--------------|------|-----------|
| 2 | 110 | .11 | milliseconds | 107 | kilobytes |
| 4 | 11,110 | 11 | milliseconds | 10.6 | megabytes |
| 6 | 10^{6} | 1.1 | seconds | 1 | gigabyte |
| 8 | 10^{8} | 2 | minutes | 103 | gigabytes |
| 10 | 10^{10} | 3 | hours | 10 | terabytes |
| 12 | 10^{12} | 13 | days | 1 | petabyte |
| 14 | 10^{14} | 3.5 | years | 99 | petabytes |
| 16 | 10^{16} | 350 | years | 10 | exabytes |

Figure 3.13 Time and memory requirements for breadth-first search. The numbers shown assume branching factor b = 10; 1 million nodes/second; 1000 bytes/node.

Uniform-cost search

<u>Uniform-cost search</u> also does a queue, but uses a priority queue based on the cost (the lowest cost node is chosen to be explored)

Uniform-cost search

The only modification is when exploring a node we cannot disregard it if it has already been explored by another node

We might have found a shorter path and thus need to update the cost on that node

We also do not terminate when we find a goal, but instead when the goal has the lowest cost in the queue.

Uniform-cost search

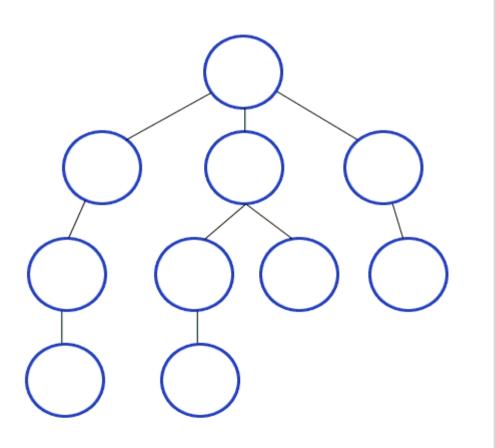

UCS is..

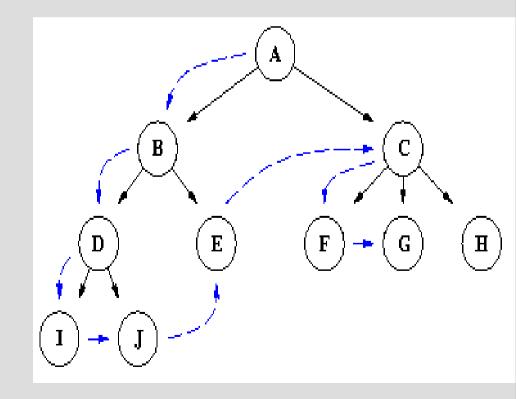

Complete (if costs strictly greater than 0)
 Optimal

However.... 3&4. Time complexity = space complexity = $O(b^{1+C*/min(path cost)})$, where C* cost of optimal solution (much worse than BFS)

Depth first search

DFS is same as BFS except with a FILO (or LIFO) instead of a FIFO queue

Depth first search

Metrics:

- 1. Might not terminate (not correct) (e.g. in vacuum world, if first expand is action L)
- 2. Non-optimal (just... no)
- 3. Time complexity = $O(b^m)$
- 4. Space complexity = O(b*m)

Only way this is better than BFS is the space complexity...

Depth limited search

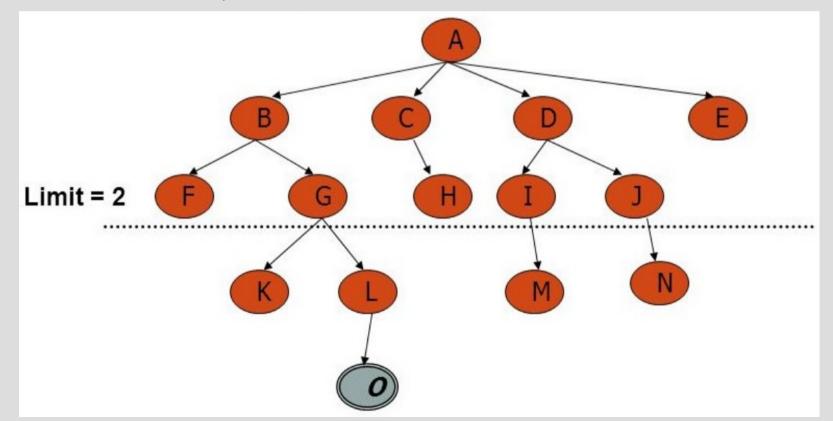

DFS by itself is not great, but it has two (very) useful modifications

<u>Depth limited search</u> runs normal DFS, but if it is at a specified depth limit, you cannot have children (i.e. take another action)

Typically with a little more knowledge, you can create a reasonable limit and makes the algorithm correct

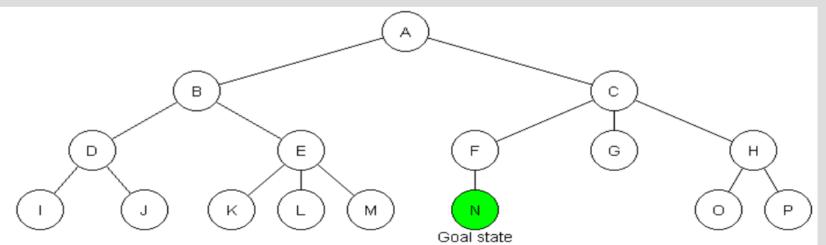

Depth limited search

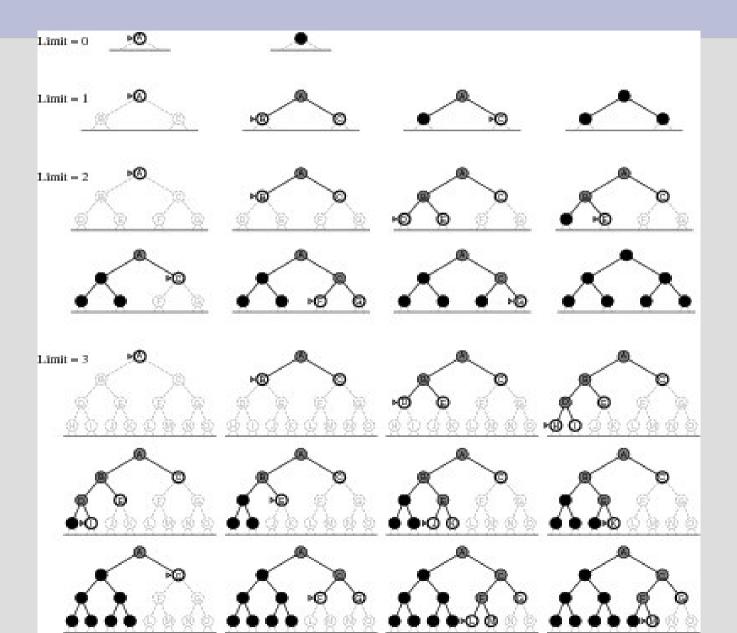

However, if you pick the depth limit before d, you will not find a solution (not correct, but will terminate)

Probably the most useful uninformed search is <u>iterative deepening DFS</u>

This search performs depth limited search with maximum depth 1, then maximum depth 2, then 3... until it finds a solution

The first few states do get re-checked multiple times in IDS, however it is not too many

When you find the solution at depth d, depth 1 is expanded d times (at most b of them)

The second depth are expanded d-1 times (at most b² of them)

Thus $d \cdot b + (d - 1) \cdot b^2 + ... + 1 \cdot b^d = O(b^d)$

Metrics: 1. Complete 2. Non-optimal (unless uniform cost) 3. O(b^d) 4. O(b*d)

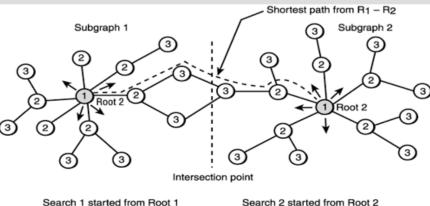

Thus IDS is better in every way than BFS (asymptotically)

Best theoretical uninformed we will talk about

Bidirectional search

<u>Bidirectional search</u> starts from both the goal and start (using BFS) until the trees meet

This is better as $2*(b^{d/2}) < b^d$ (the space is much worse than IDS, so only applicable to small problems)

Order of visitation: 1, 2, 3, ...

Summary of algorithms Fig. 3.21, p. 91

| Ci. | | 6 | | | | 2 |
|-----------|--------------------|-------------------------|--------------------|--------------------|-------------------------------|----------------------------------|
| Criterion | Breadth- First | Uniform- Cost | Depth- First | Depth- Limited | Iterative Deepening DLS | Bidirectional (if applicable) |
| Complete? | Yes[a] | Yes[a,b] | No | No | Yes[a] | Yes[a,d] |
| Time | O(b ^d) | $O(b^{1+C^*/\epsilon})$ | O(b ^m) | O(b ^I) | O(b ^d) | O(b ^{d/2}) |
| Space | O(b ^d) | $O(b^{1+C^*/\epsilon})$ | O(bm) | O(bl) | O(bd) | O(b ^{d/2}) |
| Optimal? | Yes[c] | Yes | No | No | Yes[c] | Yes[c,d] |
| | | | | | - | |

There are a number of footnotes, caveats, and assumptions.

See Fig. 3.21, p. 91.

- [a] complete if b is finite
- [b] complete if step costs $\geq \varepsilon > 0$
- [c] optimal if step costs are all identical

(also if path cost non-decreasing function of depth only)

[d] if both directions use breadth-first search

(also if both directions use uniform-cost search with step costs $\geq \varepsilon > 0$)

Generally the preferred uninformed search strategy
