LARGE SPARSE EIGENVALUE PROBLEMS

- Projection methods
- The subspace iteration
- Krylov subspace methods: Arnoldi and Lanczos
- Golub-Kahan-Lanczos bidiagonalization

14-

General Tools for Solving Large Eigen-Problems

- Projection techniques Arnoldi, Lanczos, Subspace Iteration;
- Preconditioninings: shift-and-invert, Polynomials, ...
- Deflation and restarting techniques
- ➤ Computational codes often combine these three ingredients

A few popular solution Methods

- Subspace Iteration [Now less popular sometimes used for validation]
- Arnoldi's method (or Lanczos) with polynomial acceleration
- ullet Shift-and-invert and other preconditioners. [Use Arnoldi or Lanczos for $(A-\sigma I)^{-1}$.]
- Davidson's method and variants, Jacobi-Davidson
- Specialized method: Automatic Multilevel Substructuring (AMLS).

Projection Methods for Eigenvalue Problems

Projection method onto $oldsymbol{K}$ orthogonal to $oldsymbol{L}$

- Given: Two subspaces \boldsymbol{K} and \boldsymbol{L} of same dimension.
- Approximate eigenpairs λ , \tilde{u} , obtained by solving:

Find: $\tilde{\lambda} \in \mathbb{C}, \tilde{u} \in K$ such that $(\tilde{\lambda}I - A)\tilde{u} \perp L$

Two types of methods:

Orthogonal projection methods: Situation when L = K.

Oblique projection methods: When $L \neq K$.

First situation leads to Rayleigh-Ritz procedure

Gvl4 10.1,10.5.1 – Eigen3

Procedure:

- 1. Obtain an orthonormal basis of X
- 2. Compute $C = Q^H A Q$ (an $m \times m$ matrix)
- 3. Obtain Schur factorization of C, $C = YRY^H$
- 4. Compute $\tilde{\boldsymbol{U}} = \boldsymbol{Q}\boldsymbol{Y}$

Property: if X is (exactly) invariant, then procedure will yield exact eigenvalues and eigenvectors.

Proof: Since X is invariant, $(A - \tilde{\lambda}I)u = Qz$ for a certain z. $Q^HQz=0$ implies z=0 and therefore $(A-\tilde{\lambda}I)u=0$.

Can use this procedure in conjunction with the subspace obtained from subspace iteration algorithm

Rayleigh-Ritz projection

Given: a subspace X known to contain good approximations to eigenvectors of A.

Question: How to extract 'best' approximations to eigenvalues/ eigenvectors from this subspace?

Answer: Orthogonal projection method

- ightharpoonup Let $Q=[q_1,\ldots,q_m]=$ orthonormal basis of X
- Orthogonal projection method onto X yields:

$$Q^H(A- ilde{\lambda}I) ilde{u}=0 \
ightarrow$$

- $ightharpoonup Q^H A Q y = \tilde{\lambda} y$ where $\tilde{u} = Q y$
- Known as Rayleigh Ritz process

Gvl4 10.1,10.5.1 - Eigen3

Subspace Iteration

Original idea: projection technique onto a subspace of the form $Y = A^k X$

Practically: A^k replaced by suitable polynomial

Advantages: • Easy to implement (in symmetric case);

• Easy to analyze;

Disadvantage: Slow.

 \triangleright Often used with polynomial acceleration: A^kX replaced by $C_k(A)X$. Typically $C_k=$ Chebyshev polynomial.

Gvl4 10.1,10.5.1 - Eigen3

Gvl4 10.1,10.5.1 - Eigen3

Algorithm: Subspace Iteration with Projection

- 1. Start: Choose an initial system of vectors $X = [x_0, \ldots, x_m]$ and an initial polynomial C_k .
- 2. Iterate: Until convergence do:
- (a) Compute $\hat{Z} = C_k(A)X$. [Simplest case: $\hat{Z} = AX$.]
- (b) Orthonormalize \hat{Z} : $[Z,R_Z]=qr(\hat{Z},0)$
- (c) Compute $B = Z^H A Z$
- (d) Compute the Schur factorization $B=YR_BY^H$ of B
- (e) Compute X := ZY.
- (f) Test for convergence. If satisfied stop. Else select a new polynomial $C'_{k'}$ and continue.

KRYLOV SUBSPACE METHODS

THEOREM: Let $S_0 = span\{x_1, x_2, \ldots, x_m\}$ and assume that S_0 is such that the vectors $\{Px_i\}_{i=1,\ldots,m}$ are linearly independent where P is the spectral projector associated with $\lambda_1, \ldots, \lambda_m$. Let \mathcal{P}_k the orthogonal projector onto the subspace $S_k = span\{X_k\}$. Then for each eigenvector u_i of $A, i=1,\ldots,m$, there exists a unique vector s_i in the subspace S_0 such that $Ps_i = u_i$. Moreover, the following inequality is satisfied

$$\|(I - \mathcal{P}_k)u_i\|_2 \le \|u_i - s_i\|_2 \left(\left|\frac{\lambda_{m+1}}{\lambda_i}\right| + \epsilon_k\right)^k, \quad (1)$$

where ϵ_k tends to zero as k tends to infinity.

14-9

$Krylov\ subspace\ methods$

Principle: Projection methods on Krylov subspaces:

$$K_m(A,v_1)=\mathsf{span}\{v_1,Av_1,\cdots,A^{m-1}v_1\}$$

- The most important class of projection methods [for linear systems and for eigenvalue problems]
- ullet Variants depend on the subspace $oldsymbol{L}$
- \blacktriangleright Let $\mu = \deg$ of minimal polynom. of v_1 . Then:
- $ullet K_m = \{p(A)v_1|p= ext{polynomial of degree} \leq m-1\}$
- $ullet K_m = K_\mu$ for all $m \geq \mu$. Moreover, K_μ is invariant under A.
- $dim(K_m) = m$ iff $\mu > m$.

14-10

$Arnoldi's \ algorithm$

- \triangleright Goal: to compute an orthogonal basis of K_m .
- ightharpoonup Input: Initial vector v_1 , with $\|v_1\|_2=1$ and m.

ALGORITHM: 1. Arnoldi's procedure

For
$$j=1,...,m$$
 do Compute $w:=Av_j$ For $i=1,...,j$, do $\left\{egin{aligned} h_{i,j}:=(w,v_i)\ w:=w-h_{i,j}v_i\ v_{j+1}=w/h_{j+1,j} \end{aligned}
ight.$ End

Based on Gram-Schmidt procedure

14-12 _____ Gvl4 10.1,10.5.1 – Eigen

14-1

Application to eigenvalue problems

- lacksquare Write approximate eigenvector as $ilde{u}=V_m y$
- Galerkin condition:

$$(A- ilde{\lambda}I)V_my \perp \mathcal{K}_m \quad o \quad V_m^H(A- ilde{\lambda}I)V_my = 0$$

ightharpoonup Approximate eigenvalues are eigenvalues of H_m

$$H_m y_j = ilde{\lambda}_j y_j$$

Associated approximate eigenvectors are

$$ilde{u}_i = V_m y_i$$

➤ Typically a few of the outermost eigenvalues will converge first.

F-14 Gvl4 10.1,10.5.1 – Eigen3

Result of Arnoldi's algorithm

Results:

- 1. $V_m = [v_1, v_2, ..., v_m]$ orthonormal basis of K_m .
- 2. $AV_m = V_{m+1}\overline{H}_m = V_mH_m + h_{m+1,m}v_{m+1}e_m^T$
- 3. $V_m^T A V_m = H_m \equiv \overline{H}_m$ last row.

14-13

Hermitian case: The Lanczos Algorithm

➤ The Hessenberg matrix becomes tridiagonal :

$$A=A^H$$
 and $V_m^HAV_m=H_m$ $ightarrow H_m=H_m^H$

ightharpoonup Denote H_m by T_m and $ar{H}_m$ by $ar{T}_m$. We can write

ightharpoonup Relation $AV_m=V_{m+1}\overline{T_m}$

4-15 Gvl4 10.1,10.5.1 – Eigen3

➤ Consequence: three term recurrence

$$eta_{j+1}v_{j+1}=Av_j-lpha_jv_j-eta_jv_{j-1}$$

ALGORITHM: 2. Lanczos

1. Choose an initial v_1 with $||v_1||_2=1$;

Set
$$\beta_1 \equiv 0, v_0 \equiv 0$$

- 2. For j = 1, 2, ..., m Do:
- $3. w_j := Av_j \beta_j v_{j-1}$
- 4. $\alpha_j := (w_j, v_j)$
- $5. w_i := w_i \alpha_i v_i$
- 6. $eta_{j+1}:=\|w_j\|_2$. If $eta_{j+1}=0$ then Stop
- 7. $v_{j+1} := w_j/\beta_{j+1}$
- 8. EndDo

Hermitian matrix + Arnoldi \rightarrow Hermitian Lanczos

Gvl4 10.1,10.5.1 - Eigen3

14-16

Reorthogonalization

- Full reorthogonalization reorthogonalize v_{j+1} against all previous v_i 's every time.
- Partial reorthogonalization reorthogonalize v_{j+1} against all previous v_i 's only when needed [Parlett & Simon]
- ightharpoonup Selective reorthogonalization reorthogonalize v_{j+1} against computed eigenvectors [Parlett & Scott]
- No reorthogonalization Do not reorthogonalize but take measures to deal with 'spurious' eigenvalues. [Cullum & Willoughby]

- In theory v_i 's defined by 3-term recurrence are orthogonal.
- However: in practice severe loss of orthogonality;

Observation [Paige, 1981]: Loss of orthogonality starts suddenly, when the first eigenpair has converged. It is a sign of loss of linear independence of the computed eigenvectors. When orthogonality is lost, then several the copies of the same eigenvalue start appearing.

14-17

Gvl4 10.1,10.5.1 - Eigen3

14-17

$Lanczos\ Bidiagonalization$

 \triangleright We now deal with rectangular matrices. Let $A \in \mathbb{R}^{m \times n}$.

ALGORITHM: 3. Golub-Kahan-Lanczos

1. Choose an initial v_1 with $||v_1||_2 = 1$;

Set
$$eta_0 \equiv 0, u_0 \equiv 0$$

- 2. For $k=1,\ldots,p$ Do:
- $3. \quad \hat{u} := Av_k \beta_{k-1}u_{k-1}$
- 4. $\alpha_k = \|\hat{u}\|_2$; $u_k = \hat{u}/\alpha_k$
- 5. $\hat{v} = A^T u_k \alpha_k v_k$
- 6. $\beta_k = \|\hat{v}\|_2$; $v_{k+1} := \hat{v}/\beta_k$
- 7. EndDo

Let:

$$egin{aligned} V_{p+1} &= [v_1, v_2, \cdots, v_{p+1}] &\in \mathbb{R}^{n imes (p+1)} \ U_p &= [u_1, u_2, \cdots, u_p] &\in \mathbb{R}^{m imes p} \end{aligned}$$

-19 ______ Gvl4 10.1,10.5.1 - Eigen3

Let:
$$B_p = \begin{bmatrix} \alpha_1 & \beta_1 & & & \\ & \alpha_2 & \beta_2 & & & \\ & & \ddots & \ddots & \\ & & & \alpha_p & \beta_p \end{bmatrix};$$

$$\blacktriangleright \hat{B}_p = B_p(:,1:p)$$

$$egin{aligned} \hat{B}_p &= B_p(:,1:p) \ lacksquare V_p &= [v_1,v_2,\cdots,v_p] \ lacksquare \mathbb{R}^{n imes p} \end{aligned}$$

Result:

$$V_{p+1}^T V_{p+1} = I$$

$$\triangleright U_p^T U_p = I$$

$$ightharpoonup AV_p = U_p \hat{B}_p$$

$$egin{array}{cccc} igwedge & V_{p+1}^T V_{p+1} = I \ igwedge & U_p^T U_p = I \ igwedge & AV_p = U_p \hat{B}_p \ igwedge & A^T U_p = V_{p+1} B_p^T \end{array}$$

Gvl4 10.1,10.5.1 - Eigen3

Observe that : $A^T(AV_p) = A^T(U_p\hat{B}_p)$ $=V_{p+1}B_{n}^{T}\hat{B}_{p}$

 $igwedge B_p^T \hat{B}_p$ is a (symmetric) tridiagonal matrix of size (p+1) imes p

 $(A^TA)V_p=V_{p+1}\overline{T_p}$ Call this matrix $\overline{T_k}$. Then:

Standard Lanczos relation!

Algorithm is equivalent to standard Lanczos applied to A^TA .

Similar result for the u_i 's [involves AA^T]

Work out the details: What are the entries of $ar{T}_p$ relative to those of B_p ?

Gvl4 10.1,10.5.1 - Eigen3
