CSci 5271 Introduction to Computer Security Day 14: Electronic voting

Stephen McCamant University of Minnesota, Computer Science & Engineering

Outline

Elections and their security

- Announcements intermission
- System security of electronic voting
- End-to-end verification
- Some classic network attacks

Elections as a challenge problem

- Elections require a tricky balance of openness and secrecy
- Important to society as a whole
 But not a big market
- Computer security experts react to proposals that seem insecure

History of US election mechanisms

- For first century or so, no secrecy
 Secret ballot adopted in late 1800s
- Punch card ballots allowed machine counting
 Common by 1960s, as with computers
 - still common in 2000, decline thereafter
- How to add more technology and still have high security?

Election integrity

- Tabulation should reflect actual votes
 - No valid votes removed
 - No fake votes inserted
- 🖲 Best: attacker can't change votes
- Easier: attacker can't change votes without getting caught

Secrecy, vote buying and coercion

- Alice's vote can't be matched with her name (unlinkable anonymity)
- Alice can't prove to Bob who she voted for (receipt-free)
- Best we can do to discourage:
 - Bob pays Alice \$50 for voting for Charlie
 - Bob fires Alice if she doesn't vote for Charlie

Election verifiability

- We can check later that the votes were tabulated correctly
- Alice, that her vote was correctly cast
- Anyone, that the counting was accurate
- In paper systems, "manual recount" is a privileged operation

Politics and elections In a stable democracy, most candidates will be "pro-election"

- But, details differ based on political realities
- "Voting should be easy and convenient"
 Especially for people likely to vote for me
- "No one should vote who isn't eligible" Especially if they'd vote for my opponent

Errors and Florida

Detectable mistakes:

Overvote: multiple votes in one race
 Undervote: no vote in a race, also often intentional
 Undetectable mistakes: vote for wrong candidate
 2000 presidential election in Florida illustrated all these, "wake-up call"

Precinct-count optical scan

- Good current paper system, used here in MN
- 🖲 Voter fills in bubbles with pen
- Ballot scanned in voter's presence Can reject on overvote
- Paper ballot retained for auditing

Vote by mail

By mail universal, e.g. in Oregon and Washington

- Many other states have lenient absentee systems
 - Some people are legitimately absent
- Security perspective: makes buying/coercion easy Doesn't appear to currently be a big problem

Vote by web?

- 🖲 An obvious next step
- But, further multiplies the threats
- No widespread use in US yet
- Unusual adversarial test in D.C. thoroughly compromised by U. Michigan team

DRE (touchscreen) voting

"Direct-recording electronic": basically just a computer that presents and counts votes
 In US, touchscreen is predominant interface
 Cheaper machines may just have buttons
 Simple, but centralizes trust in the machine

Adding an audit trail

- 🖲 VVPAT: voter-verified paper audit trail
- DRE machine prints a paper receipt that the voter looks at
- Goal is to get the independence and verifiability of a paper marking system

Outline

Elections and their security

Announcements intermission

System security of electronic voting

End-to-end verification

Some classic network attacks

Midterm exam Wednesday

- Midterm exam Wednesday in class, starting promptly at 1:00pm
- Six solution sets for old exams now posted

Invitations out for meetings tomorrow through Friday

- See you in Keller or over Zoom
- Other email discussions also ongoing

Outline

Elections and their security

Announcements intermission

System security of electronic voting

End-to-end verification

Some classic network attacks

Trusted client problem

- Everything the voter knows is mediated by the machine
 - (For Internet or DRE without VVPAT)
- Must trust machine to present and record accurately

🖲 A lot can go wrong

- Especially if the machine has a whole desktop OS inside
- Or a bunch of poorly audited custom code

Should we use DRE at all?

🖲 One answer: no, that's a bad design

- More pragmatic: maybe we can make this work
 - DREs have advantages in cost, disability access
 - If we implemented them well, they should be OK
 - Challenge: evaluating them in advance

US equipment market

- Voting machines are low volume, pretty expensive
- But jurisdictions are cost-conscious
- Makers are mostly small companies
 - One was temporarily owned by the larger Diebold
- Big market pressures: regulations, ease of administration

Security ecosystem

Voting fraud appears to be very rare

- Few elections worth stealing
- Important ones are watched closely
- Stiff penalties deter in-US attackers
- Downside: No feedback from real attacks
- Main mechanism is certification, with its limitations

Diebold case study Major manufacturer in early 2000s During a post-2000 purchasing boom Since sold and renamed Thoroughly targeted by independent researchers Impolitic statement, blood in the water Later state-authorized audits found comprehensive

- Later state-authorized audits found comprehensity problems
 - Your reading: from California

Physical security

- Locked case; cheap lock as in hotel mini-bar
- Device displays management menu on detected malfunction
 - Can be triggered in booth by unspecified use of paperclip
- Tamper-evident seals? Not a strong protection

Web-like vulnerabilities

In management workstation software:

- SQL injection
- Authentication logic encoded only in enabled/disabled UI elements
 - E.g., buttons grayed out if not administrator
 - Not quite as obviously wrong as in web context
 - But still exploitable with existing tools

Secrecy problems

- Limited, since the DRE doesn't see registration information
- But, records timestamp and order of voting
- Could be correlated with hidden camera or corrupted poll worker

Voting machine viruses

- Two-way data flow between voting and office machines
- Hijacking vuln's in software on both sides
- ${\color{black} \bullet} {\color{black} \to} {\color{black} \circ} {\color{black} \bullet} {\color{$
- Leverage small amount of physical access

Subtle ways to steal votes

- Change a few votes your way, revert if the voter notices
 - Compare: flip coin to split lunch
- Control the chute for where VVPAT receipts go
- Exchange votes between provisional and regular voters

Outline

Elections and their security

Announcements intermission

System security of electronic voting

End-to-end verification

Some classic network attacks

Commitment to values

- Two phases: commit, later open Similar to one use of envelopes
- Binding property: can only commit to a single value
- E) Hiding property: value not revealed until opened

Randomized auditing

- How can I prove what's in the envelope without opening it?
- n envelopes, you pick one and open the rest
 Chance 1/n of successful cheating
- Better protection with repetition

Election mix-nets

- Independent election authorities similar to anonymous remailers
- Multi-encrypt ballot, each authority shuffles and decrypts
- Extra twist: prove no ballots added or removed, without revealing permutation
 - Instance of "zero-knowledge proof"
- Privacy preserved as long as at least one authority is honest

Pattern voting attack

- Widely applicable against techniques that reveal whole (anonymized) ballots
- Even a single race, if choices have enough entropy
 3-choice IRV with 35 candidates: 15 bits
- Buyer says: vote first for Bob, then 2nd and 3rd for Kenny and Xavier
 - Chosen so ballot is unique

Fun tricks with paper: visual crypto

- Want to avoid trusted client, but voters can't do computations by hand
- Analogues to crypto primitives using physical objects
- One-time pad using transparencies:

Scantegrity II

- Designed as end-to-end add-on to optical scan system
- Fun with paper 2: invisible ink

Single trusted shuffle

Checked by random audits of commitments

Outline

- Elections and their security
- Announcements intermission
- System security of electronic voting
- End-to-end verification

Some classic network attacks

Forging packet sources

- Source IP address not involved in routing, often not checked
- Change it to something else!
- Might already be enough to fool a naive UDP protocol

TCP spoofing

Forging source address only lets you talk, not listen

- Old attack: wait until connection established, then DoS one participant and send packets in their place
- Frustrated by making TCP initial sequence numbers unpredictable
 - But see Oakland'12, WOOT'12 for fancier attacks, keyword "off-path"

ARP spoofing

- Impersonate other hosts on local network level
- Typical ARP implementations stateless, don't mind changes
- Now you get victim's traffic, can read, modify, resend

rlogin and reverse DNS

- rlogin uses reverse DNS to see if originating host is on allow-list
- How can you attack this mechanism with an honest source IP address?

rlogin and reverse DNS

- rlogin uses reverse DNS to see if originating host is on allow-list
- How can you attack this mechanism with an honest source IP address?
- Remember, ownership of reverse-DNS is by IP address
