Writing 1 graded, regrades due April 1

Homework 3 posted, due on Sunday at end of spring break (3/24)

Game theory

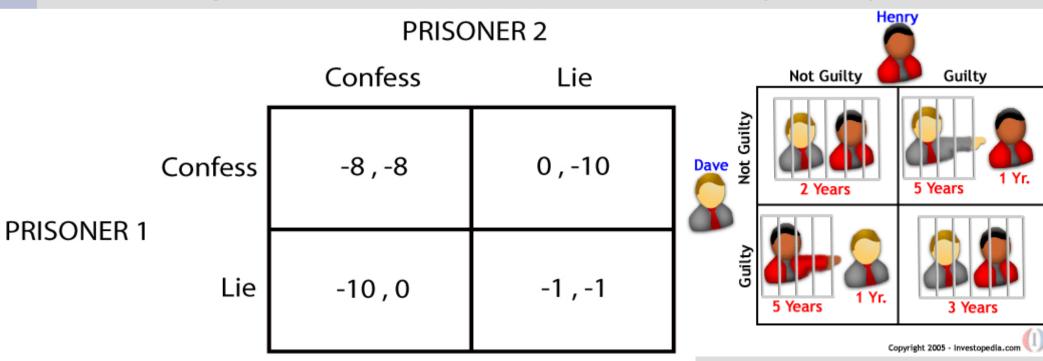

Typically game theory uses a <u>payoff matrix</u> to represent the value of actions

The first value is the reward for the left player, right for top (positive is good for both)

Here is the famous "prisoner's dilemma"

Each player chooses one action without knowing the other's and the is only played once

What option would you pick?

Why?

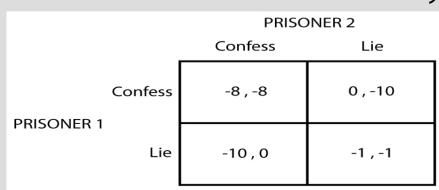

What would a rational agent pick?

If prisoner 2 confesses, we are in the first column... -8 if we confess, or -10 if we lie --> Thus we should confess

If prisoner 2 lies, we are in the second column,

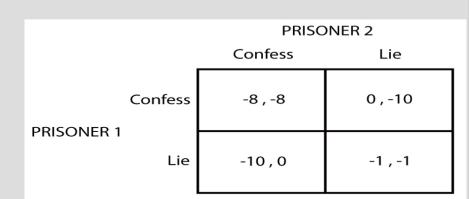

- 0 if we confess,
- -1 if we lie
- --> We should confess

It turns out regardless of the other player's action, it is in our personal interest to confess

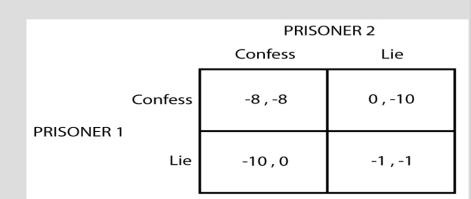

This is the <u>Nash equilibrium</u>, as any deviation of strategy (i.e. lying) can result in a lower score (i.e. if opponent confesses)

The Nash equilibrium looks at the worst case and is greedy

Formally, a Nash equilibrium is when the combined strategies of all players give no incentive for any single player to change

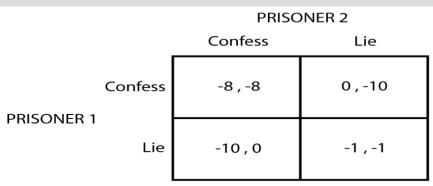

In other words, if any single person decides to change strategies, they cannot improve

Alternatively, a <u>Pareto optimum</u> is a state where no other state can result in a gain or tie for all players (excluding all ties)

If the PD game, [-8, -8] is a Nash equilibrium, but is not a Pareto optimum (as [-1, -1] better for both players)

However [-10,0] is also a Pareto optimum...

Every game has at least one Nash equilibrium and Pareto optimum, however...

- Nash equilibrium might not be the best outcome for all players (like PD game, assumes no cooperation)
- A Pareto optimum might not be stable (in PD the [-10,0] is unstable as player 1 wants to switch off "lie" and to "confess" if they play again or know strategy)

Find the Nash and Pareto for the following: (about lecturing in a certain csci class)

Ctudont

	Stu	Jeni
- -	pay attention	sleep
prepare well	5, 5	-2, 2
slack off	1, -5	0, 0

Teacher

How do we formally find a Nash equilibrium?

If it is zero-sum game, can use minimax as neither player wants to switch for Nash (our PD example was not zero sum)

Let's play a simple number game: two players write down either 1 or 0 then show each other. If the sum is odd, player one wins. Otherwise, player 2 wins (on even sum)

This gives the following payoffs:

Dial 1 Player 2

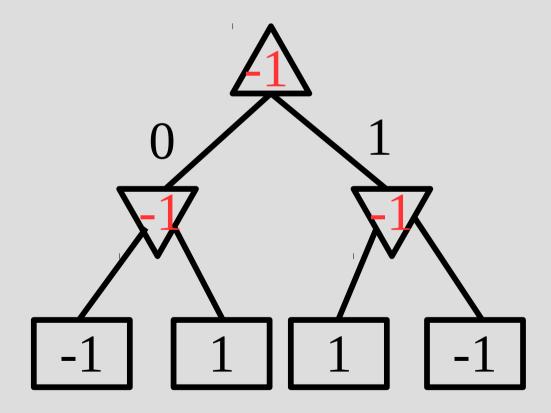

Dlavor 1	Pick 0	Pick 1 ^{Play}
Player 1 Pick 0	-1, 1	1, -1
Pick 1	1, -1	-1, 1

(player 1's value first, then player 2's value)

We will run minimax on this tree twice:

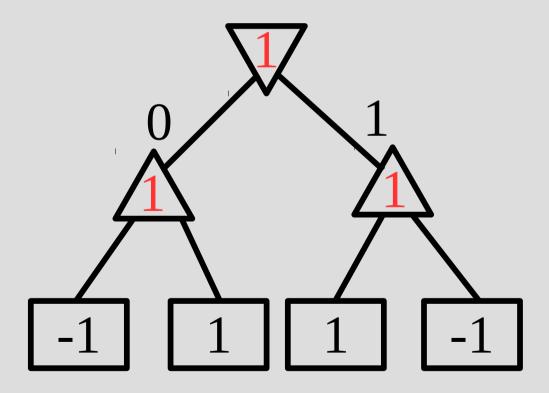

- 1. Once with player 1 knowing player 2's move (i.e. choosing after them)
- 2. Once with player 2 knowing player 1's move

Player 1 to go first (max):

If player 1 goes first, it will always lose

Player 2 to go first (min):

If player 2 goes first, it will always lose

This is not useful, and only really tells us that the best strategy is between -1 and 1 (which is fairly obvious)

This minimax strategy can only find pure strategies (i.e. you should play a single move 100% of the time)

To find a mixed strategy, we need to turn to linear programming

A <u>pure strategy</u> is one where a player always picks the same strategy (deterministic)

A <u>mixed strategy</u> is when a player chooses actions probabilistically from a fixed probability distribution (i.e. the percent of time they pick an action is fixed)

If one strategy is better or equal to all others across all responses, it is a <u>dominant strategy</u>

The definition of a Nash equilibrium is when no one has an incentive to change the combined strategy between all players

So we will only consider our opponent's rewards (and not consider our own)

This is a bit weird since we are not considering our own rewards at all, which is why the Nash equilibrium is sometimes criticized

First we parameterize this and make the tree stochastic:

Player 1 will choose action "0" with probability p, and action "1" with (1-p)

(-1)p + (1)(1-p)

If player 2 always picks 0, so the payoff for p2: (1)p + (-1)(1-p)
If player 2 always picks 1, so the payoff for p2:

Plot these two lines:

$$U = (1)p + (-1)(1-p)$$

$$U = (-1)p + (1)(1-p)$$

As we maximize, the pick blue opponent gets to pick for this p which line to play

Thus we choose the intersection

opponent pick red for this p

Thus we find that our best strategy is to play 0 half the time and 1 the other half

The result is we win as much as we lose on average, and the overall game result is 0

Player 2 can find their strategy in this method as well, and will get the same 50/50 strategy (this is not always the case that both players play the same for Nash)

We have two actions, so one parameter (p) and thus we look for the intersections of lines

If we had 3 actions (rock-paper-scissors), we would have 2 parameters and look for the intersection of 3 planes (2D)

This can generalize to any number of actions (but not a lot of fun)

		Player 2		
		Stone	Paper	Scissors
	Stone	(0,0)	(-1,1)	(1,-1)
Player 1	Paper	(1, -1)	(0, 0)	(-1,1)
	Scissors	(-1,1)	(1,-1)	(0,0)

How does this compare on PD?

	Confess	ess Lie	
Confess	-8 , -8	0,-10	
Lie	-10,0	-1 , -1	

Player 1: p = prob confess...

P2 Confesses: -8*p + 0*(1-p)

P2 Lies: -10*p + (-1)*(1-p)

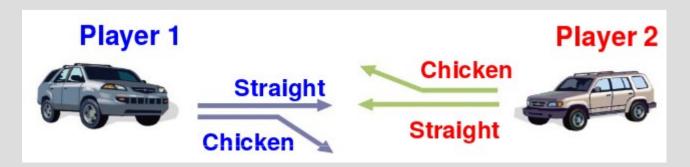

Cross at negative p, but red line is better (confess)

What is Nash for this game? What is Pareto optimum?

	S	С
S	-10, -10	1, -1
C	-1, 1	0, 0

Game of Chicken

To find Nash, assume we (blue) play S probability p, C prob 1-p

Column 1 (red=S): p*(-10) + (1-p)*(1) Column 2 (red=C): p*(-1) + (1-p)*(0)

Intersection: -11*p + 1 = -p, p = 1/10

Conclusion: should always go straight 1/10 and chicken 9/10 the time

We can see that 10% straight makes the opponent not care what strategy they use:

```
(Red numbers)
100\% straight: (1/10)*(-10) + (9/10)*(1) = -0.1
100\% chicken: (1/10)*(-1) + (9/10)*(0) = -0.1
50\% straight: (0.5)*[(1/10)*(-10) + (9/10)*(1)]
+ (0.5)*[(1/10)*(-1) + (9/10)*(0)]
= (0.5)*[-0.1] + (0.5)*[-0.1] = -0.1
```

The opponent does not care about action, the considered our values)

Your rewards, opponent 100% straight:

$$(0.1)*(-10) + (0.9)*(-1) = -1.9$$

Your rewards, opponent 100% curve:

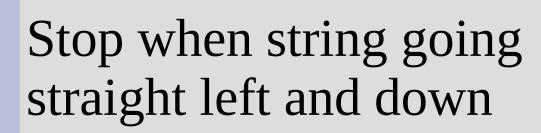

$$(0.1)*(1) + (0.9)*(0) = 0.1$$

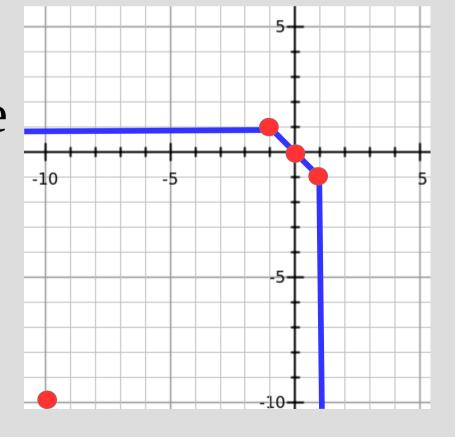

The opponent also needs to play at your value intersection to achieve Nash

Pareto optimum? All points except (-10,10)

S		С
S	-10, -10	1, -1
C	-1, 1	0, 0

Can think about this as taking a string from the top right and bringing the it down & left

Repeated games

In repeated games, things are complicated

For example, in the basic PD, there is no

benefit to "lying"

			PRISONER 2	
			Confess	Lie
Con PRISONER 1	Confess	-8,-8	0,-10	
	Lie	-10,0	-1 , -1	

However, if you play this game multiple times, it would be beneficial to try and cooperate and stay in the [lie, lie] strategy

Repeated games

One way to do this is the tit-for-tat strategy:

- 1. Play a cooperative move first turn
- 2. Play the type of move the opponent last played every turn after (i.e. answer competitive moves with a competitive one)

This ensure that no strategy can "take advantage" of this and it is able to reach cooperative outcomes

Repeated games

Two "hard" topics (if you are interested) are:

- 1. We have been talking about how to find best responses, but it is very hard to take advantage if an opponent is playing a sub-optimal strategy
- 2. How to "learn" or "convince" the opponent to play cooperatively if there is an option that benefits both (yet dominated)
