Game theory (Ch. 17.5)

How do we formally find a Nash equilibrium?

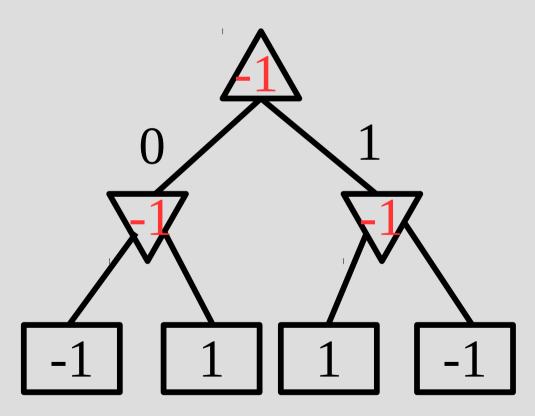

If it is zero-sum game, can use minimax as neither player wants to switch for Nash (our PD example was not zero sum)

Let's play a simple number game: two players write down either 1 or 0 then show each other. If the sum is odd, player one wins. Otherwise, player 2 wins (on even sum)

This gives the following payoffs:
Pick 0Player 1
Pick 0Pick 1Player 1
Pick 0-1, 11, -11, -1Pick 11, -1

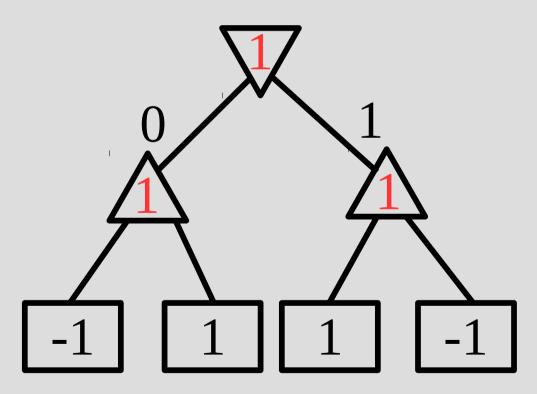

(player 1's value first, then player 2's value)
We will run minimax on this tree twice:
1. Once with player 1 knowing player 2's move (i.e. choosing after them)
2. Once with player 2 knowing player 1's move

Player 1 to go first (max):

If player 1 goes first, it will always lose

Player 2 to go first (min):

If player 2 goes first, it will always lose

This is not useful, and only really tells us that the best strategy is between -1 and 1 (which is fairly obvious)

This minimax strategy can only find pure strategies (i.e. you should play a single move 100% of the time)

To find a mixed strategy, we need to turn to linear programming

A <u>pure strategy</u> is one where a player always picks the same action (row/col) (deterministic)

A <u>mixed strategy</u> is when a player chooses actions probabilistically from a fixed probability distribution (i.e. the percent of time they pick an action is fixed)

If one strategy is better or equal to all others across all responses, it is a <u>dominant strategy</u>

The definition of a Nash equilibrium is when no one has an incentive to change the combined strategy between all players

So we will only consider our opponent's rewards (and not consider our own)

This is a bit weird since we are not considering our own rewards at all, which is why the Nash equilibrium is sometimes criticized

First we parameterize this and make the tree stochastic:

Player 1 will choose action "0" with probability p, and action "1" with (1-p)

If player 2 always picks 0, so the payoff for p2:
 (1)p + (-1)(1-p)
If player 2 always picks 1, so the payoff for p2:
 (-1)p + (1)(1-p)

0.5

pick blue

for this p

0.5

onent

pick red

for this p

05

Plot these two lines: U = (1)p + (-1)(1-p)U = (-1)p + (1)(1-p)

A Nash is where the opponent doesn't want to change

Thus we choose the intersection (equal value)

Thus we find that our best strategy is to play 0 half the time and 1 the other half

The result is we win as much as we lose on average, and the overall game result is 0

Player 2 can find their strategy in this method as well, and will get the same 50/50 strategy (this is not always the case that both players play the same for Nash)

We have two actions, so one parameter (p) and thus we look for the intersections of lines

If we had 3 actions (rock-paper-scissors), we would have 2 parameters and look for the intersection of 3 planes (2D)

This can generalize to any number of actions (but not a lot of fun)

		Player 2		
		Stone	Paper	Scissors
Player 1	Stone	(0,0)	(-1,1)	(1,-1)
	Paper	(1, -1)	(0, 0)	(-1,1)
	Scissors	(-1,1)	(1, -1)	(0,0)

05

How does this compare on PD?

	Confess	Lie	
Confess	-8 , -8	0,-10	
Lie	-10,0	-1 , -1	

Player 1: p = prob confess... P2 Confesses: -8*p + 0*(1-p) P2 Lies: -10*p + (-1)*(1-p)

Cross at negative p, but red line is better (confess)

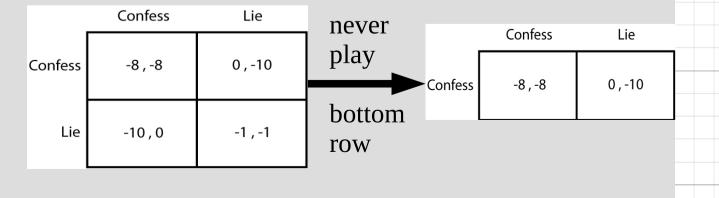

0

-1-5

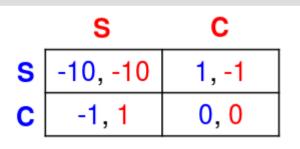

05

In cases like this where you get wonky probabilities, it means there is a dominant strategy

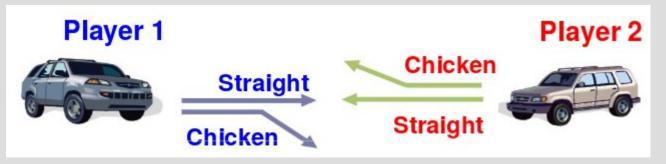

You should then remove the dominated action and recalc.

What is Nash (pure and mixed) for this game? What is Pareto optimum?

Game of Chicken

To find Nash, assume we (blue) play S probability p, C prob 1-p

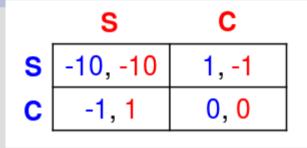

Column 1 (red=S): $p^{(-10)} + (1-p)^{(1)}$ Column 2 (red=C): $p^{(-1)} + (1-p)^{(0)}$

Intersection: -11*p + 1 = -p, p = 1/10

Conclusion: should always go straight 1/10 and chicken 9/10 the time

We can see that 10% straight makes the opponent not care what strategy they use:

(Red numbers) 100% straight: $(1/10)^{*}(-10) + (9/10)^{*}(1) = -0.1$ 100% chicken: $(1/10)^{*}(-1) + (9/10)^{*}(0) = -0.1$ 50% straight: $(0.5)^{*}[(1/10)^{*}(-10) + (9/10)^{*}(1)]$ $+ (0.5)^{*}[(1/10)^{*}(-1) + (9/10)^{*}(0)]$ $= (0.5)^{*}[-0.1] + (0.5)^{*}[-0.1] = -0.1$

The opponent does s c not care about action, d s c s -10, -10 1, -1 but you still do (never considered our values)

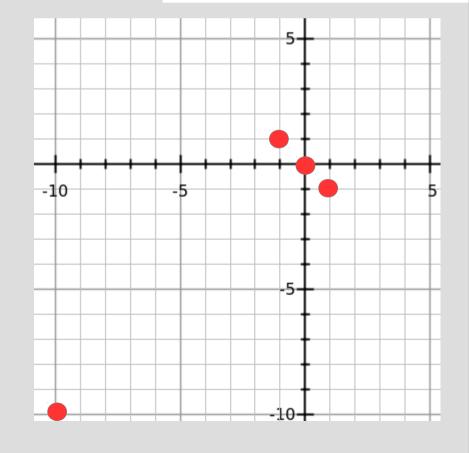

Your rewards, opponent 100% straight: $(0.1)^*(-10) + (0.9)^*(-1) = -1.9$ Your rewards, opponent 100% curve: $(0.1)^*(1) + (0.9)^*(0) = 0.1$ The opponent also needs to play at your value intersection to achieve Nash

Pareto optimum? All points except (-10,10)

Going off the definition, P1 loses point if move off (1,-1) ... similar P2 on (-1,1)

At (0,0) there is no point with both vals positive

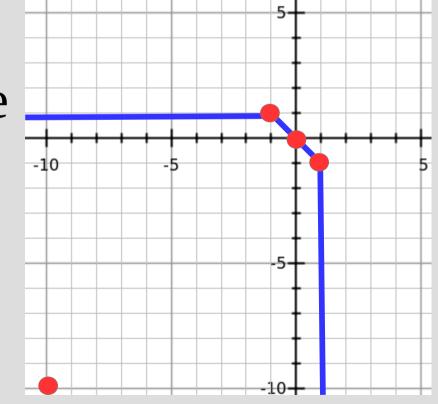

We can define a mixed strategy Pareto optimal points

Can think about this as taking a string from the top right and bringing the it down & left

Stop when string going straight left and down

We have two actions, so one parameter (p) and thus we look for the intersections of lines

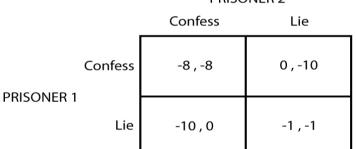

If we had 3 actions (rock-paper-scissors), we would have 2 parameters and look for the intersection of 3 planes (2D)

This can generalize to any number of actions (but not a lot of fun)

		Player 2		
		Stone	Paper	Scissors
Player 1	Stone	(0,0)	(-1,1)	(1,-1)
	Paper	(1, -1)	(0, 0)	(-1,1)
	Scissors	(-1,1)	(1, -1)	(0,0)

In repeated games, things are complicated

For example, in the basic PD, there is no benefit to "lying"

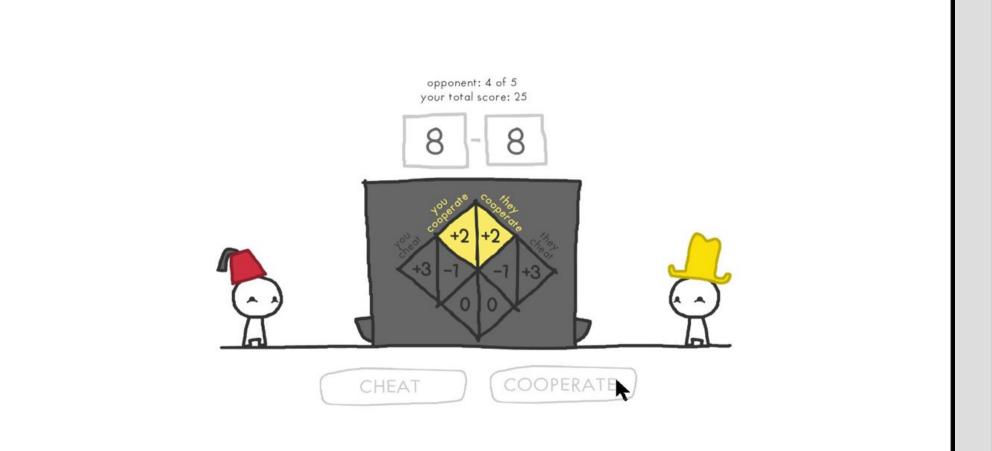

However, if you play this game multiple times, it would be beneficial to try and cooperate and stay in the [lie, lie] strategy

One way to do this is the <u>tit-for-tat</u> strategy:
1. Play a cooperative move first turn
2. Play the type of move the opponent last played every turn after (i.e. answer competitive moves with a competitive one)

This ensure that no strategy can "take advantage" of this and it is able to reach cooperative outcomes

Two "hard" topics (if you are interested) are:

- 1. We have been talking about how to find best responses, but it is very hard to take advantage if an opponent is playing a sub-optimal strategy
- 2. How to "learn" or "convince" the opponent to play cooperatively if there is an option that benefits both (yet dominated)
